When it comes to the performance of wireless routers, most customers will tend to focus on the wireless speed they get on the main channels. TP-LINK has a long and storied history in the arena of wireless networking, and one of their first models, the TL-WR841N, was one of the first routers to really justify the name "N" in network. Performance of devices like this are always important because there will be users who do not have the capability to perform complex tasks. The WR841N, for instance, allowed users to run 2 SSIDs on the 5 GHz network and the other on the 2.4 GHz network. To do that on a traditional router, you have to use a separate mode and the multiple SSID feature on each of the two access points. Since the WR841N, TP-LINK has released a number of models with the N moniker attached to their name and many of the features of the former 841N are now included in TP-LINK's newer wireless offerings. Most of the newer routers have the dual band feature and typically deliver up to a theoretical 450Mbps peak speed on 2.4 GHz and up to 300Mbps on 5 GHz depending on the frequency bands available. This particular model only has a dual band feature, so the peak speeds are limited to 300Mbps on 5 GHz and only 150Mbps on 2.4 GHz. Note that due to FCC regulations, it is not possible to put a dual band router on the 2.4 GHz and 5 GHz network at the same time. This issue has caused manufacturers to limit the number of SSIDs on each band. Typically, most dual band routers will allow you to run 1 SSID on the 2.4 GHz band and one on the 5 GHz band. The WR2543N has four SSIDs that can be used on both bands, so you can control access to two separate networks on each band. To complete the installation of TP-LINK, you must first check that you have a flat hard surface on which to place the hardware. It is important
