1. Field of the Invention The present invention relates to a numerical controller. More specifically, the present invention relates to a numerical controller used for a production line or the like. 2. Description of the Related Art In a numerically controlled machine tool, it is generally necessary to set in accordance with instructions, such as NC data, a speed of cutting or a speed of feeding a work, in order to prevent generation of a correction error which would otherwise occur due to the following reason. When a worker performs cutting work by a cutting tool by using a machine tool, the worker usually performs work while looking at an operator area, and watches a cutting surface of the cutting tool. Thereby, information on the position of the cutting tool is learned. However, when the worker performs cutting work, it is required to carry out cutting while looking at the operator area and watching the cutting surface of the cutting tool. Thereby, the worker may easily suffer injury or accident. To solve the problem, for example, a numerical controller provided with an automatic cutting work range judgment function is disclosed in Japanese Patent

Unexamined Publication (Kokai) No. 2007-276147. However, with the conventional numerical controller, since the automatic cutting work range judgment function is merely provided, it is impossible to avoid detection of a danger such as an edge of a tool or a dangerous point in a machine tool while a tool is being held or a complicated calculation is carried out for processing of a control program, or the like. Further, when using such a numerical controller, even though it is possible to detect a danger, it is impossible to avoid generating a control signal for controlling the tool. Accordingly, it is not possible to promptly respond to generation of a control signal for driving a tool. As a result, it is conceivable that there is a possibility of danger.Lifestyle Community Made in Canada Gorgeous Kitchen Appliances & Lighting Ceramic Tile Backsplash | Time for a Paint Job? which, for example, are in poor inner city areas of the United States, which had significantly less wealth, median wealth and net worth at all income levels. It is important to remember that the average income of such families was $10,500, which was greater than the average overall income in the United States for that year. Key to the paper's analysis was some simple history of technology. The bulk of the analysis was based on the paper's own histories of technologies and the changes therein. The paper notes that everything in the past was a few years behind and that there were some short term disruptions in the time line, but that this was pretty normal, at least from the economic point of view. It is interesting to note that in some cases the technology innovation that took place was what we would today call "frictionless", that is, involving only the transfer of funds, with the use of the funds being determined by the market, not by either party. Paper is interested in the early examples because these were the first to involve real disruption to existing economic patterns. This disruptive "edge technology" was as follows: Inventions as described may seem somewhat quixotic, but by 1810, some 20 years after the Revolutionary War,

inventors were writing letters asking for financial and legal help in getting their money. The man who made many of these famous inventions most likely lived in a time and place when sending mail was a time consuming, difficult process that sometimes took months or even years to complete. The paper then goes on to describe an example of the impact of such innovations on the economy. It is interesting that they do not quite come out and discuss why these innovative solutions would only appear in the poorer regions, but perhaps that is an obvious point to make. A number of these innovations were actually for the most part free. Once such example is in the case of the ball bearing. The paper notes that it is an example of "real" innovation, but the paper notes that this innovation (the ball bearing) was not wildly expensive but rather was under $1.00 US. This paper is interesting in many regards, including the technical points discussed. But, most notably, it does a great job of highlighting the importance of these innovators in our economy. It was their innovations, which often were not worth much, but were very difficult to create or implement, which created a barrier to entry for large, well established business and economic interests
